Abstract

The purpose of this senior thesis is to examine the relationships that rare diseases and experimental treatments have on psychosocial development. This research is focused on a case study I completed and presented on a teenage girl, during which I learned about cystinuria, auto-renal transplants, and adolescent psychosocial development. Auto-renal transplants have only recently and rarely been performed to alleviate the pain and some of the damage caused by the passing of cystine kidney stones. This paper considers one of the newest medical procedures and its effectiveness in terms of a patient with chronic cystinuria.

Acknowledgements

I'd like to thank the Radiology Child Life team at Children's Memorial Hospital for inspiring me to become a Child Life Specialist when I was a patient myself. I'd like to thanks Tracy Byler, CCLS and Lindsay Bromberg, CCLS for being my Child Life mentors and for helping me to attain each Child Life education milestone, big or small. My parents have always encouraged me to follow my dreams, even when my goal is to be in the narrow and competitive field of Child Life and for that I could not be more grateful. And, of course, I'd like to thank my thesis advisor Dr. Lindberg for her willingness to be my thesis advisor, and especially for her patience throughout this process.
